1	Pointers	2
1.1	Declaring and Defining Pointers	2
1.2	Using Pointers	2

1 Pointers

A **pointer** is a variable that represents a memory address, often the address of another variable. Pointers “point” to locations in memory and allow indirect access to the values stored there.

1.1 Declaring and Defining Pointers

To declare a pointer, use an asterisk `*` and specify the type of data it points to:

```
1 int* ptr; // declares a pointer to an int
```

To make a pointer “point” to a variable, use the address-of operator `&`:

```
1 int* ptr;  
2 int x {};  
3 ptr = &x; // 'point' ptr to the address of x
```

1.2 Using Pointers

To access the value pointed to, we use the dereference operator `*`:

dereference.cpp

```
1 #include <iostream>  
2  
3 int main()  
4 {  
5     int x { 42 };  
6     int* ptr { &x };  
7     std::cout << "x = " << *ptr << std::endl;  
8 }
```

Terminal

```
$ clang++ -std=c++23 dereference.cpp  
$ ./a.out  
x = 42
```

Since pointers provide direct memory access, they can also be used to modify variables indirectly:

increment.cpp

```
1 #include <iostream>  
2  
3 int main()  
4 {  
5     int x { 42 };  
6     int* ptr { &x };  
7     (*ptr)++;  
8     std::cout << "x = " << x << std::endl;  
9 }
```

Terminal

```
$ clang++ -std=c++23 increment.cpp  
$ ./a.out  
x = 43
```
